(Dated: Received date; Accepted date)

We report the result of our ab initio calculation of the $6s^2S_{1/2} \rightarrow 5d^2D_{3/2}$ parity nonconserving electric dipole transition amplitude in $^{137}\text{Ba}^+$ based on relativistic coupled-cluster theory. Considering single, double and partial triple excitations, we have achieved an accuracy of less than one percent. If the accuracy of our calculation can be matched by the proposed parity nonconservation experiment in Ba$^+$ for the above transition, then the combination of the two results would provide an independent non accelerator test of the Standard Model of particle physics.

Parity nonconservation (PNC) in atoms arising from neutral weak currents has the potential to test the Standard Model (SM) of particle physics [1, 2]. By combining the results of high precision measurements and calculations of atomic PNC observables, it is possible to extract the nuclear weak charge [2] and compare with its corresponding value in the SM. A discrepancy between these two values could reveal the possible existence of new physics beyond the SM. The most accurate data on atomic PNC currently comes from the $6s^2S_{1/2} \rightarrow 7s^2S_{1/2}$ transition in cesium (Cs), where the claimed experimental [3] and theoretical [4] accuracies are 0.35% and 0.5% respectively and the deviation from the SM is about 1σ [4]. It would indeed be desirable to consider other candidates which could yield accurate values of the nuclear weak charge. In this context an observable PNC in the $6s^2S_{1/2} \rightarrow 5d^2D_{3/2}$ transition in Ba$^+$ using the techniques of ion trapping and laser cooling proposed by Fortson is of special importance [4, 5].

This Letter is concerned with a high precision calculation of the amplitude of the above mentioned parity nonconserving electric dipole (E1$_{\text{PNC}}$) transition in Ba$^+$ using relativistic coupled-cluster (RCC) theory, which is equivalent to all order relativistic many-body perturbation theory [6]. It is the first application of this theory to atomic PNC. Blundell et al had used this theory in the linear approximation to calculate E1$_{\text{PNC}}$ for the $6s^2S_{1/2} \rightarrow 7s^2S_{1/2}$ transition in Cs [6]. Dzuba et al [7] and Geetha [10] have calculated this PNC amplitude for the $6s^2S_{1/2} \rightarrow 5d^2D_{3/2}$ transition in Ba$^+$ as discussed later.

The parity nonconserving nuclear spin independent (NSI) interaction arises from the nucleon-electron neutral weak interaction and its Hamiltonian is given by

$$H^\text{NSI}_{\text{PNC}} = \frac{G_F}{2\sqrt{2}} Q_w \gamma_5 \rho_N(r)$$

(0.1)

where $G_F$ is the Fermi constant, $Q_w$ is the nuclear weak charge which is equal to $[(2Z+N)c_{1u} + (2N+Z)c_{1d}]$ with $c_{1u}$ and $c_{1d}$ representing electron-up-quark and electron-down-quark coupling constants respectively, $\rho_N(r)$ is the nuclear density function and $\gamma_5(=i\gamma_0\gamma_1\gamma_2\gamma_3)$, which is a pseudo-scalar, is the product of the four Dirac matrices. $H^\text{NSI}_{\text{PNC}}$ is responsible for mixing atomic states of opposite parities but with the same angular momentum. Its strength is sufficiently weak for it to be considered as a first-order perturbation. It is therefore possible to write the $n$'th state atomic wavefunction as

$$|\Psi_n\rangle = |\Psi_n^{(0)}\rangle + G_F |\Psi_n^{(1)}\rangle$$

(0.2)

In RCC, the atomic wavefunction $|\Psi_v^{(0)}\rangle$ for a single valence ($v$) open-shell system is given by [8, 11]

$$|\Psi_v^{(0)}\rangle = e^{T(0)^v} \{ 1 + S_v^{(0)} \} |\Phi_v\rangle$$

(0.3)

where we define $|\Phi_v\rangle = a_v^+ |\Phi_0\rangle$, with $|\Phi_0\rangle$ as the Dirac-Fock (DF) state for closed-shell system. In the singles and doubles approximation we have

$$T^{(0)} = T_1^{(0)} + T_2^{(0)}$$

$$S_v^{(0)} = S_{1v}^{(0)} + S_{2v}^{(0)}$$

(0.4)

where $T_1^{(0)}$ and $T_2^{(0)}$ are the single and double particle-hole excitation operators for core electrons and $S_{1v}^{(0)}$ and $S_{2v}^{(0)}$ are the single and double excitation operators for the valence electron respectively. The amplitudes corresponding to these operators can be determined by solving
the relativistic coupled-cluster singles and doubles equations. A subset of important triple excitations have been considered in the determination of the open shell amplitudes \(S_{1v}^{(0)}\) and \(S_{2v}^{(0)}\) which is described in \[12\] \[13\].

Using eqn. (0.2), the explicit form of \(E_{1\text{PNC}}\) is given by

\[
E_{1\text{PNC}} = \frac{\langle \Psi_f | D | \Psi_i \rangle}{\sqrt{\langle \Psi_f | \Psi_f \rangle}} = \frac{\langle \Psi_f^{(0)} | D | \Psi_i^{(1)} \rangle + \langle \Psi_f^{(1)} | D | \Psi_i^{(0)} \rangle}{\sqrt{\langle \Psi_f^{(0)} | \Psi_f^{(0)} \rangle}} \tag{0.5}
\]

where \(D\) is the electric dipole (E1) operator, \(i\) and \(f\) subscripts are used for initial and final valence electrons respectively. Using the explicit expression for the first order perturbed wavefunction, we get

\[
E_{1\text{PNC}} = \sum_{I \neq i} \frac{\langle \Psi_f^{(0)} | D | \Psi_i^{(1)} \rangle \langle \Psi_i^{(0)} | H_{\text{PNC}}^{\text{NSI}} | \Psi_f^{(0)} \rangle}{E_i - E_I}
+ \sum_{I \neq f} \frac{\langle \Psi_f^{(0)} | H_{\text{PNC}}^{\text{NSI}} | \Psi_i^{(0)} \rangle \langle \Psi_i^{(0)} | D | \Psi_f^{(0)} \rangle}{E_f - E_I} \tag{0.6}
\]

where \(I\) represent intermediate states.

It is obvious from the above equation that, the accuracy of the calculation of \(E_{1\text{PNC}}\) depends on the excitation energies of the different intermediate states, the matrix elements of \(H_{\text{PNC}}^{\text{NSI}}\) and \(D\). Blundell et al have used the above equation to determine \(E_{1\text{PNC}}\) for the 6s²S₁/2 → 7s²S₁/2 transition in Cs by considering the most important intermediate states \[8\]. The drawback of this approach is that the summation can be performed only over a finite set of intermediate states which limits the accuracy of the calculation. The method we have used in the present work circumvents this problem by solving the first order perturbed equation

\[
(H^{(0)} - E^{(0)}) | \Psi_v^{(1)} \rangle = (E^{(1)} - H_{\text{PNC}}^{\text{NSI}}) | \Psi_v^{(0)} \rangle. \tag{0.7}
\]

where \(E^{(1)}\) vanishes for first order correction.

The perturbed cluster operators can be written as

\[
T = T^{(0)} + G_F T^{(1)},
S_v = S_v^{(0)} + G_F S_v^{(1)} \tag{0.8}
\]

where \(T^{(1)}\) and \(S_v^{(1)}\) are the first order \(G_F\) corrections to the cluster operators \(T^{(0)}\) and \(S_v^{(0)}\) respectively. The amplitudes of these operators are solved, keeping up to linear in PNC perturbed amplitudes, by the following equations

\[
\langle \Phi_v | H_N^{(0)} T^{(1)} + H_{\text{PNC}}^{\text{NSI}} | \Phi_v \rangle = 0,
\langle \Phi_v^{(1)} | H_N^{(0)} T^{(1)} + H_{\text{PNC}}^{\text{NSI}} | \Phi_v \rangle = -\langle \Phi_v | S_v^{(0)} | \Phi_v \rangle, \tag{0.9}
\]

and

\[
\langle \Phi_v^{(1)} | H_N^{(0)} S_v^{(1)} + H_{\text{PNC}}^{\text{NSI}} | \Phi_v \rangle = -\langle \Phi_v | S_v^{(0)} | \Phi_v \rangle, \tag{0.10}
\]

where \(H^{(0)}\) is the Dirac-Coulomb (DC) Hamiltonian and \(\mathbf{P}\) is defined as \(e^{-T^{(0)} H^{(0)}}\) which is computed after determining \(T^{(0)}\), IP is the ionization potential energy corresponding to the valence electron \('v'\) and the sub-script \(N\) denotes normal form of an operator. We have used \(a, b,.., p, q,..\) etc. to represent holes and particles respectively. \(| \Phi_v \rangle\) and \(| \Phi_v^{(1)} \rangle\) are the single and double excited states respectively with respect to \(| \Phi_v \rangle\). Using Eqs. (0.3), (0.5), (0.8) and only keeping terms linear in \(G_F\), the expression for \(E_{1\text{PNC}}\) can be written as

\[
E_{1\text{PNC}} = \frac{\langle \Phi_f | (1 + S_f^{(0)}) T^{(1)} S_f^{(1)} + T^{(1)} S_f^{(0)} T^{(1)} | \Phi_i \rangle}{\sqrt{(1 + N_f^{(0)}) (1 + N_i^{(0)})}}
+ \frac{\langle \Phi_f | D^{(0)} (1 + S_f^{(0)}) + (1 + S_f^{(0)}) D^{(0)} S_f^{(1)} + S_f^{(0)} T^{(1)} D^{(0)} + D^{(0)} T^{(1)} S_f^{(0)} + (T^{(1)} D^{(0)} + D^{(0)} T^{(1)}) S_f^{(0)} | \Phi_i \rangle}{\sqrt{(1 + N_f^{(0)}) (1 + N_i^{(0)})}} \tag{0.11}
\]

In the above expression we define \(D^{(0)} = e^{-T^{(0)} D^{(0)}}\) and \(N_v^{(0)} = S_v^{(0)} e^{-T^{(0)} S_v^{(0)}}\) for the valence electron \('v'\) and each term is connected. The above matrix element is evaluated by a method similar to that used in our earlier works of Ba⁺ \[14\] \[15\].

The orbitals are constructed as linear combinations of Gaussian type orbitals (GTOs) of the form \[16\]

\[
F_{i,k}(r) = r^k e^{-\alpha_i r^2}. \tag{0.12}
\]

where \(k = 0, 1,..,\) for s,p,... type orbital symmetries respectively. For the exponents, we have used

\[
\alpha_i = \alpha_0 q^{i-1} \tag{0.13}
\]

We have considered 30s₁/₂, 25p₁/₂, 25p₃/₂, 25d₃/₂, 25d₅/₂, 20f₅/₂, 20f₇/₂, 20g₇/₂ and 20g₉/₂ GTOs for the
distribution approximation given by

\[ \rho = \frac{\rho_0}{1 + e^{(r - r_0)/a}} \]  \hspace{1cm} (0.14)\]

where \( \rho_0 \) is the average nuclear density, ‘c’ is the half
charge radius, and ‘a’ is related to the skin thickness.

Our earlier calculations of excitation energies \[ \text{Expt. [17]} \] E1 transition amplitudes \[ \text{Expt. [18]} \] and magnetic dipole hyperfine constants \[ \text{Expt. [19, 20, 21]} \] for some of the low-lying states in Ba\(^+\) based on RCC theory suggest that it is in principle possible to perform a calculation of E1\(_{\text{PNC}}\) for the 6s\(^2\)S\(_{1/2}\) → 5d\(^2\)D\(_{3/2}\) transition in that ion to an accuracy of better than one percent. We have recalculated these quantities using the same method but with a larger basis and the results are given in table I. The agreement with experiment of the most important excitation energy (6p\(^2\)P\(_{1/2}\)) for the calculation of E1\(_{\text{PNC}}\) is less than one percent. This is also the case for the hyperfine constants of three of the states – 6p\(^2\)P\(_{1/2}\), 6p\(^2\)P\(_{3/2}\) and 5d\(^2\)D\(_{3/2}\), while for the 6s\(^2\)S\(_{1/2}\) state, the agreement is a little over one percent. All the transition amplitudes are within the experimental error bars. The result of our calculation of the electric quadrupole (E2) amplitude for the 6s\(^2\)S\(_{1/2}\) → 5d\(^2\)D\(_{3/2}\) transition is 12.61 in a.u. It is in agreement with our earlier calculation \[ \text{Expt. [14]} \] and well within the experimental bounds \[ \text{Expt. [22]} \]. In table II, we present the values of the square root of the product of the hyperfine constants. The accuracies of these two quantities give an indication of the accuracies of the PNC matrix elements between 6s\(^2\)S\(_{1/2}\) and 6p\(^2\)P\(_{1/2}\) states as well as 6p\(^2\)P\(_{3/2}\) and 5d\(^2\)D\(_{3/2}\) states. Both of them are in excellent agreement with experiment, suggesting that the two leading PNC matrix elements used in the E1\(_{\text{PNC}}\) calculation are very accurate. The contributions from the different terms in E1\(_{\text{PNC}}\) are presented in table III. It is clear that the largest contribution comes from D\(_{1}^{(1)}\) (diagram 1(iii)) which represents the DF term and a certain sub class of core polarization as well as pair correlation effects \[ \text{Expt. [14]} \]. This is due to the relatively large (6s\(^2\) − 6p\(^2\)) S\(_{1}^{(1)}\) cluster amplitude. Two different types of core polarization effects; DT\(_{1}^{(1)}\) (diagram 1(i)) and DS\(_{2}^{(1)}\) as well as its conjugate (diagrams 1(iv) and 1(vi)) also make significant contributions. The former is mediated by the neutral weak interaction and involves the 6s valence and core electrons. Correlation effects corresponding to S\(_{1}^{(0)}\) D\(_{1}^{(1)}\) and S\(_{1}^{(0)}\) D\(_{1}^{(1)}\) are negligible, but their signs are opposite. Contributions from other terms are comparatively small.

The result of E1\(_{\text{PNC}}\) for the 6s\(^2\)S\(_{1/2}\) → 5d\(^2\)D\(_{3/2}\) transition in our calculation is 2.46 × 10\(^{-11}\) in a.u. It is larger in magnitude than those obtained by Dzuba et al \[ \text{Expt. [4]} \] and Geetha \[ \text{Expt. [11]} \] as shown by table IV. The former work is based on a variant of all order many-body perturbation theory, but it has some semi-empirical features. It is carried out by using two different approaches. One of them is similar to the sum-over-states approach by Blundell et al \[ \text{Expt. [6]} \] and the other is known as the mixed approach where the PNC interaction explicitly mixes states of opposite parities. However, both calculations do not include contributions from certain correlation effects; i.e. structural radiation, weak correlation potential and normalization of states \[ \text{Expt. [6]} \] that are included in our calculation. Their 6p\(^2\)P\(_{1/2}\) → 5d\(^2\)D\(_{3/2}\) E1 matrix element which is important for the above mentioned PNC

\[ \Delta H_{\text{PNC}}^{\text{NSI}} = 2.018 \quad \Delta H_{\text{PNC}}^{\text{NSI-D}} = -0.3 \times 10^{-5} \]
The error accrued in our calculation of $E_{1PNC}$ can be determined from the errors in the excitation energies, E1 transition amplitudes and hyperfine constants (see table I). We have not estimated the errors in the calculated values of these quantities by comparing with measurements, since the error bars in the E1 transition amplitudes are rather large. Instead, we have taken the differences of our RCC calculations with single, double and leading triple excitations and just single and double excitations as the errors. The error in $E_{1PNC}$ (0.02) has been obtained by adding the errors for the different quantities it depends on in quadrature for the leading intermediate states $6p^{2}P_{1/2}$ and $6p^{2}P_{3/2}$ and using a scale factor to estimate the errors from other intermediate states that together make a small contribution.

The contribution of the Breit interaction to $E_{1PNC}$ at the DF level is 0.1% and the nuclear structure contribution is 0.3%. The latter has been determined more accurately than Blundell et al. using relativistic mean field theory.

In conclusion, we have performed a sub one percent calculation of $E_{1PNC}$ for the $6s^{2}S_{1/2} \rightarrow 5d^{2}D_{3/2}$ transition in Ba$^{+}$ using RCC. We have included single, double as well as a leading class of triple excitations and highlighted the importance of various many-body effects. Given the promise that the Ba$^{+}$ PNC experiment holds out, it does indeed appear that in the future the result of that experiment combined with our calculation would constitute a new and an important probe of physics beyond the SM.

We acknowledge discussions with G. Gopakumar. We would like to thank Prof. N. Fortson and J. Sherman for useful communications. We are grateful to Prof. J. Kluge for his critical reading of the paper. BK thanks DAAD for his scholarship. The calculation was carried out using the Terra-flopp Supercomputer in C-DAC, Bangalore.

transition amplitude is not as accurate as ours. Furthermore, the accuracies of their PNC matrix elements are not known as they have not performed calculations of the hyperfine constants of the relevant states. The reason for the discrepancy between our calculation and Geetha’s is that our approach implicitly includes several intermediate states; particularly doubly excited opposite parity states which her sum-over-states approach omits.
